

# DJANGO REST FRAMEWORK

BY MOHAMMAD HASAN KHODDAMI

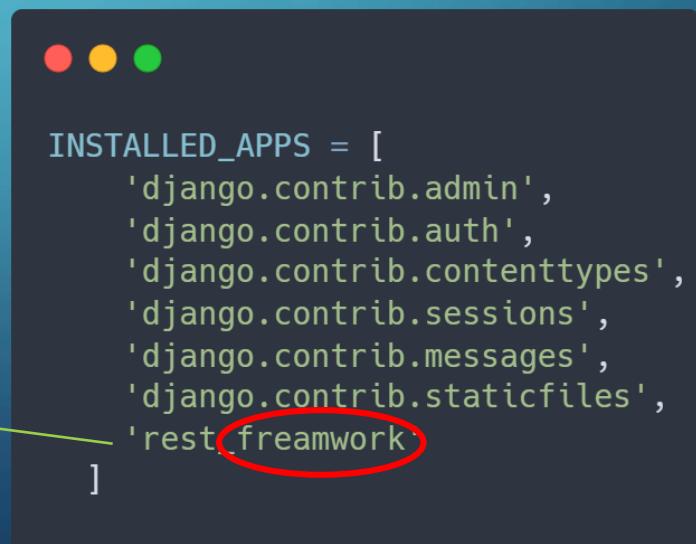

# WHAT WE GONNA LEARN

- 1- DRF for sure !
- 2- creating document by swagger
- 3- using Postman

# HOW TO INSTALL DRF ?

- By using following command :
  - Pip install djangorestfremwork
- Also you have to introduce it into installed apps on setting.py

The correct is framework

```
INSTALLED_APPS = [
    'django.contrib.admin',
    'django.contrib.auth',
    'django.contrib.contenttypes',
    'django.contrib.sessions',
    'django.contrib.messages',
    'django.contrib.staticfiles',
    'rest_freamwork'
]
```

# REQUEST AND RESPONSE STRUCTURE IN DRF

- Request : extends httprequest
- Now what httprequest ? → the request that we claim from the client are instances from httprequest which give us some option like : the method of the incoming request, figuring out who is the client, authentication and etc...

# REQUEST.DATA AND REQUEST.QUERY\_PARAMS

- In DRF instead of having `request.files` and `request.post` we have `request.data`
- Query params are the query which used in url and we can have access to that
- Also we know about `request.user`

# RESPONSE

- As we know **every request has a response**
- Our response are the instances from **response class**
- The built in function for sending response is :
- Response (**data, ...** ) , just data is necessary
- Data param in response Is native python`s data types like dictionary or list or tuple or etc...
- Response won`t serialize for us. Response take the native python`s data type and change it to Json and send it to request

# CREATE VIEW

- As you know we have 2 type of function FBV and CBV in DRF also we have 2 types CBV and FBV same as Django but it's recommended to use CBV.
  - But for start we use function base view

# @API\_VIEW

Now we want to create our first view by API\_view decorator

Mistyping correct is →framework

```
● ● ●  
from rest_freamwork.decorators import api_view  
from rest_freamwork.response import Response
```

Step 1 : import api\_view and Response (as we said our responses are instances from Response class)

```
● ● ●  
@api_view()  
def hello_world(request)  
    return Response('message' : hello world)
```

Step 2 : create our function , note : we didn't define our method so by default it's GET

```
● ● ●  
@api_view(['GET' , 'POST'])  
def hello_world(request)  
    return Response('message' : hello world)
```

Step 3 : Define the methods

Step 4,5,6,7... : is creating urls just like Django.

# EXAMPLE AND ELABORATION

I wrote this code and sent it  
to Response. (note :  
Response gets native python  
data's)

```
home > views.py > hello_world
1 from django.shortcuts import render
2 from rest_framework.decorators import api_view
3 from rest_framework.response import Response
4 # Create your views here.
5
6
7 @api_view(['GET', 'POST'])
8 def hello_world(request):
9
10     production = [
11         {'name': 'phone',
12          'price': '1200'},
13         {'name': 'laptop',
14          'price': 1500}
15     ]
16     return Response(production)
```

This is the result  
DRF has default template

This is the data's which can use as API !  
Others will use it on their website !  
Done !!

The screenshot shows a browser window with a "Hello World" title. Below it is a "GET /home/" request section. The response status is "HTTP 200 OK" with headers: "Allow: POST, OPTIONS, GET", "Content-Type: application/json", and "Vary: Accept". The response body is a JSON array containing two objects:

```
[{"name": "phone", "price": "1200"}, {"name": "laptop", "price": 1500}]
```

Below the response, there is a "Media type:" dropdown set to "application/json" and a "Content:" text area. At the bottom right, there are "POST" and "OPTIONS" buttons.

# CBV IN DRF

The other settings just like Django.  
And I turn hello world FBV into CBV.

```
from rest_framework.views import APIView
```

```
class HelloWorld(APIView):
    production = [
        {'name': 'phone',
         'price': '1200'},
        {'name': 'laptop',
         'price': 1500}
    ]

    def get(self, request):
        return Response(self.production)

    def post(self, request):
        return Response(self.production)
```

# GETTING QUERY PARAMS

This is query params (after ?) and we want to create a view for it

- A. I used get built in for if there is no name return me none !
- B. I just changed Get method.

```
① 127.0.0.1:8000/home/cbv/?name=mohammad
```

```
class HelloWorld(APIView):
    production = [
        {'name': 'phone',
         'price': '1200'},
        {'name': 'laptop',
         'price': 1500}
    ]
    def get(self, request):
        name = request.GET.get('name')
        return Response({'message' : f'hello {name}'})
    def post(self, request):
        return Response(self.production)
```

# RESULT !

By using GET  
method

By using POST method give us  
the production content because  
I've changed the POST method

The screenshot shows a REST API tool interface with two main sections. The top section displays the results of a GET request, and the bottom section shows the configuration for a POST request.

**GET Request Results:**

- Method: GET (highlighted with a red circle)
- URL: /home/cbv/?name=mohammad%20hasan
- Status: HTTP 200 OK
- Headers:
  - Allow: GET, POST, HEAD, OPTIONS
  - Content-Type: application/json
  - Vary: Accept
- Response Body:

```
{  
    "message": "hello mohammad hasan"  
}
```

**POST Request Configuration:**

- Media type: application/json
- Content: (Empty text area)
- Buttons:
  - POST (highlighted with a red circle)

# INSTALLING THE POSTMAN

- Download PostMan from following link :
  - <https://www.postman.com/downloads/>
- Create an account and launch the app
- By using postman we can test our API

# POSTMAN

The screenshot shows the Postman application interface. On the left, there is a sidebar titled "My Workspace" with sections for "Collections", "Environments", and "History". A red box highlights the "Workspaces" tab in the top navigation bar. Below it, a red box highlights the "My Workspace" item in the "Recently visited" list. A large red box encloses the entire sidebar area. In the center, the main workspace shows a "Welcome to your personal workspace!" message with a cartoon illustration of a person at a desk. Below this, there are two prominent buttons: "Send an API request" (with a red box around its icon) and "Import cURL, collections, and more" (with a red box around its icon). Further down, there are three recommended templates: "REST API basics", "Integration testing", and "API documentation", each with a small icon and a brief description. The top right corner of the interface shows standard window controls (minimize, maximize, close) and status indicators.

Click on workspace  
Chose My Workspace  
Then click on send an API request  
Or press ctrl + T

Send an API request      Import cURL, collections, and more

REST API basics      Integration testing      API documentation

# POSTMAN

Sending urls for test

methods

The screenshot shows the Postman application interface. On the left, there's a sidebar with 'My Workspace' containing 'Collections' (selected), 'Environments', 'History', and a 'Create Collection' button. Below it, there's a section for creating collections with a 'Create a collection for your requests' heading and a detailed description about collections. A 'Create Collection' button is also present here.

The main area is titled 'Untitled Request' under the 'HTTP' tab. It features a dropdown menu for selecting a method ('GET' is selected). To the right of the method dropdown is a search bar labeled 'Enter URL or paste text'. Below the search bar is a table with columns for 'Value' and 'Description'. The table has rows for 'Headers (6)', 'Body', 'Pre-request Script', 'Tests', and 'Settings'. A 'Send' button is located at the bottom right of the main area.

A red callout box highlights the 'Methods' dropdown in the top-left corner of the request builder. A red arrow points from the text 'methods' in the top right towards this callout. Another red arrow points from the text 'Sending urls for test' in the top center towards the search bar.

# POSTMAN-GET

The screenshot shows the Postman application interface. On the left, the sidebar displays "My Workspace" with a collection named "My first collection". This collection contains two folders: "First folder inside collection" and "Second folder inside collection", each with several requests. A modal window titled "Create a collection for your requests" is open, explaining what a collection is and how it can group related requests. Below this, there is a "Create Collection" button.

The main workspace shows a GET request to `http://127.0.0.1:8000/home/cbv/`. The "Headers" tab shows six headers. The "Body" tab is selected, showing a JSON response:

```
1 [  
2   {  
3     "name": "phone",  
4     "price": "1200"  
5   },  
6   {  
7     "name": "laptop",  
8     "price": 1500  
9   }  
10 ]
```

The status bar at the bottom right indicates a successful response: Status: 200 OK, Time: 16 ms, Size: 393 B, and a "Save as example" button.

# POSTMAN-POST

If you want to send query\_params as post you have to use request.query\_params

```
def post(self, request):
    name = request.query_params.get('name')
    return Response({'msg' : f'hello {name}'})
```

The screenshot shows the Postman interface with a POST request to `http://127.0.0.1:8000/home/cbv/?name=mohammad`. The 'Query Params' section is highlighted with a red border. It contains a table with two rows:

Key	Value
name	mohammad
Key	Value

The response body is displayed in JSON format:

```
1  {
2   "msg": "hello mohammad"
3 }
```

# POSTMAN-POST JSON

If we want to send form-data or json content we have to use request.data in body part of post man.

```
def post(self, request):
    if request.query_params:
        name = request.query_params.get('name')
        return Response({'msg' : f'hello {name}'})
    elif request.data:
        name = request.data.get('name')
        return Response({'msg':f'hello {name}'})
```

The screenshot shows the Postman interface for a POST request to `http://127.0.0.1:8000/home/cbv/`. The 'Body' tab is active, and the 'form-data' option is selected. A single form-data entry named 'name' with value 'mohammad hasan' is present. The response body is displayed in JSON format:

```
1: {
2:     "msg": "hello mohammad hasan"
3: }
```

# FINAL CODE

```
# views.py > > HelloView > > post
from django.shortcuts import render
from rest_framework.decorators import api_view
from rest_framework.response import Response
from rest_framework.views import APIView
# Create your views here.
class HelloWorld(APIView):
    production = [
        {'name': 'phone',
         'price': '1200'},
        {'name': 'laptop',
         'price': 1500}
    ]

    def get(self, request):
        return Response(self.production)

    def post(self, request):
        if request.query_params:
            name = request.query_params.get('name')
            return Response({'msg' : f'hello {name}'})
        elif request.data:
            name = request.data.get('name')
            return Response({'msg':f'hello {name}'})
```

# CONCEPTS

- Now we want to say what is Django rest framework and how does it works?
- First of all what is Rest? Rest is an architect sample for programing
- Second of all why do we use Django rest framework?
- i`ll explain in next slide

# THAT'S WHY – REASON 1

We can create one API and connect it to database  
then we don't need to create so many database  
for each server or app

## THAT'S WHY – REASON 2

- REACT !
- Sometimes the front end is react ! And we can't connect the Django into it, therefore we have to create an API and use it as a connector.

# REST PRINCIPLES

## 6 Characteristics of a REST API

Client-Server Architecture

Statelessness

Cacheability

Layered System

Code-on-Demand

Uniform Interface

# CONCEPTS

- What is `request.data` ? It's not quite accurate question better question is what is `.data`
- `.data` are the data's which client send it to server in body part of request
- Now `request.user...` it's the same as Django we can have access to user information by `request.user`

# GETTING QUERY PARAMS AS ARGUMENT

Example :

http://127.0.0.1:8000/home/ali/ → sending query params as argument

http://127.0.0.1:8000/home/?name=ali → sending query params as query params

Note : query params are not define as argument

If we want to claim the argument we should use following settings below:

```
#urls.py
path('home/<str:name>', views.GetName.as_view(), name = 'getname')
#views.py
class GetName(APIView):
    def get(self, request, name):
        return Response({'name' : name})
```

# SERIALIZERS

- In last slides we create dictionary in views but in real world is different
  - we have to create models and models turn data's to dictionary then client could read the information for this process we can use serializers
  - Serializers allow complex data such as queryset and model instances to be converted to native python datatypes that can easily rendered to json or xml
  - Serializers also provide deserializers

# SERIALIZERS

- Step 1 : create a model
- Step 2 : create new file and name it serializers.py
- Step 3 : from rest\_framework import serializers on serializers.py
- Step 3.5 : create a class which inheritance serializers.Serializer
- Step 4 : create serializer !
- Also you can create custom field in serializer

# MODEL TO SERIALIZER

Some field are not available in serializer therefore we have to use alternatives or create custom field in drf documentation the alternative fields are defined please read that !

```
#models.py
class Person(models.Model):
    name = models.CharField(max_length=50)
    age = models.PositiveIntegerField()
    email = models.EmailField(max_length=254)

#serializer.py
from rest_framework import serializers

class PersonSerializer(serializers.Serializer):
    name = serializers.CharField()
    age = serializers.IntegerField()
    email = serializers.EmailField()
```

# USE SERIALIZERS

We create 2 user from our model in admin panel then we want to make their data readable by serializers

Writing instance is optional but I  
wrote that for better understanding

```
#views.py
from .models import Person
from .serializers import PersonSerializer
class GetName(APIView):
    def get(self, request):
        person = Person.objects.all()
        personserialize = PersonSerializer(instance= person, many = True)
        return Response({'data' : personserialize.data})
```

We can send it as context  
Or send it as native python  
data type

By default serializers  
except 1 argument when  
we send it more than 2 we  
have write : many = True

We want data so we have to  
write it !

# RESULT

Note : model data's are query set and we can use it as response

As context

```
{ "data": [ { "name": "mmd", "age": 23, "email": "mmd@gmail.com"}, { "name": "mamadkevin", "age": 32, "email": "kevin@gmail.com"} ] }
```

As python native datatype

```
[ { "name": "mmd", "age": 23, "email": "mmd@gmail.com"}, { "name": "mamadkevin", "age": 32, "email": "kevin@gmail.com"} ]
```

Note 2 : we can define id in serializers too !(but usually we don't do it)

# USER REGISTER

- Do the same thing as Django !
- Now we reach at restframework !
  - First : we don't need GET method cause information going to send therefore we need POST method
- We are going to use default Django registration model

# USER REGISTER

- Step 1 : create serializer.py
- Step 2 : create serializers
- ... then we are going into views

```
● ● ●  
from rest_framework import serializers  
  
class UserRegisterSerializer(serializers.Serializer):  
    username = serializers.CharField(required = True)  
    email = serializers.EmailField(required = True)  
    password = serializers.CharField(required = True)
```

# USER REGISTER

Import !

```
● ● ●  
from rest_framework.views import APIView  
from rest_framework.response import Response  
from .serializers import UserRegisterSerializer  
from django.contrib.auth.models import User
```

# USER REGISTER VIEW EXPLANATION

We shouldn't send serializer data ! Because client send it ! (actually we don't have any data)

```
class RegisterView(APIView):
    def post(self, request):
        user = UserRegisterSerializer(data = request.POST)
        if user.is_valid():
            User.objects.create_user(
                username= user.validated_data['username'],
                email = user.validated_data['email'],
                password = user.validated_data['password'],
            )
            return Response({'user': user.data})
        return Response(user.errors)
```

Create user

In rest framework we have validated\_data instead of cleaned\_data

There is default error of serialazors

# USER REGISTER TEST

- For testing it we using post man

And now if check admin panel we have new user

But reading password could be dangerous , therefore we adding write\_only into serializer field

The screenshot shows a Postman request for a user registration endpoint. The method is POST, and the URL is <http://127.0.0.1:8000/accounts/register/>. The 'Body' tab is selected, showing three form-data fields: 'username' (text 'mohammad'), 'email' (text 'mohammad@gmail.com'), and 'password' (text '123456'). Below the body, the response section shows a 200 OK status with a response time of 706 ms and a size of 399 B. The response body is displayed in JSON format, with the password field highlighted by a red box.

Key	Value	Description
username	mohammad	
email	mohammad@gmail.com	
password	123456	

```
1 {  
2     "user": {  
3         "username": "mohammad",  
4         "email": "mohammad@gmail.com",  
5         "password": "123456"  
6     }  
7 }
```

# USER REGISTER PASSWORD

```
#serializer.py  
password = serializers.CharField(required = True, write_only = True)
```

Result

The screenshot shows a POST request to <http://127.0.0.1:8000/accounts/register/>. The 'Body' tab is selected, showing a JSON payload:

Key	Type	Value
username	Text	mohammad123
email	Text	mohammad23@gmail.com
password	Text	123456456

Below the table, there is a preview of the JSON response:

```
1 {  
2   "user": {  
3     "username": "mohammad123",  
4     "email": "mohammad23@gmail.com"  
5   }  
6 }
```

# CUSTOM VALIDATION

- Custom validation separate in 2 method
  - 1- field level validation
  - 2- object level validation
  - 3- validators (not recommended)

# FIELD LEVEL VALIDATION

- For using field level validation we have to create a function which start by validate then writing the field that we want to validate it. Then raise validation error

```
class UserRegisterSerializer(serializers.Serializer):
    username = serializers.CharField(required = True)
    email = serializers.EmailField(required = True)
    password = serializers.CharField(required = True, write_only = True)

    def validate_username(self, value):
        if value == 'admin':
            raise serializers.ValidationError('username cannot be admin')
        return value
```

We have to return the value ,  
value is the value that we want  
validate it!

# CONFIRM PASSWORD

- For validation confirm password we have to use object level validation
  - Step 1 : I create serializer field and name it to password 2
  - Step 2 : create function which name is validate
  - Step 3 : give him data parameter
  - Step 4 : validate It as we want
  - Step 5 : return data

# CONFIRM PASSWORD

Data contains all fields in serializer so for validate a field we have to slice it !

Different between field level and object level is object level is the data that client send it

```
class UserRegisterSerializer(serializers.Serializer):
    username = serializers.CharField(required = True)
    email = serializers.EmailField(required = True)
    password = serializers.CharField(required = True, write_only = True)
    password2 = serializers.CharField(required = True, write_only = True)

    def validate(self, data):
        if data['password'] != data['password2']:
            raise serializers.ValidationError('passwords must be match')
        return data
```

# VALIDATORS

- A. create a function out of the class
- B. send the function to target serializer field as a tuple

# VALIDATORS

```
● ● ●  
  
def clean_email(value):  
    if 'admin' in value:  
        raise serializers.ValidationError('admin can`t be in email')  
    return value  
  
class UserRegisterSerializer(serializers.Serializer):  
    username = serializers.CharField(required = True)  
    email = serializers.EmailField(required = True, validators = [clean_email])  
    password = serializers.CharField(required = True, write_only = True)  
    password2 = serializers.CharField(required = True, write_only = True)
```

# MODEL SERIALIZERS

- Model serializers is like MODELFORM in Django
- As we can remember model form in Django used for turning model into from for updating or creating the content in the form
- Therefore we don't need to create a manual serializer

# MODEL SERIALIZER

```
class UserRegisterSerializer(serializers.ModelSerializer):
    class Meta:
        model = User
        fields = ('username', 'email', 'password')
```

Instead of naming the fields we can use “`__all__`”

And if we want all fields except one field we can use `excludes = (“name_of_field”)`

# EXTRA KWARGS

- So we use `modelserializer` therefore we don't have direct access to fields. So now how we can set `write_only` for password or give the email field our function ? Answer : → By using `extra kwargs`

```
● ● ●  
class UserRegisterSerializer(serializers.ModelSerializer):  
    class Meta:  
        model = User  
        fields = ('username', 'email', 'password')  
        extra_kwargs = {  
            'password': {'write_only' : True},  
            'email' : {'validators': [clean_email]}  
        }
```

Extra\_kwargs is  
nested dictionary

# ADDING FIELD

- For password confirm we need password 2 field but we don't have it ... so what should we do ? We have to create it ! Then have to add it into fields

```
● ● ●  
class UserRegisterSerializer(serializers.ModelSerializer):  
    password_2 = serializers.CharField(write_only = True)  
  
    class Meta:  
        model = User  
        fields = ('username', 'email', 'password', 'password2')  
        extra_kwargs = {  
            'password': {'write_only' : True},  
            'email' : {'validators': [clean_email]}  
    }
```

# OVERRIDE CLEAN

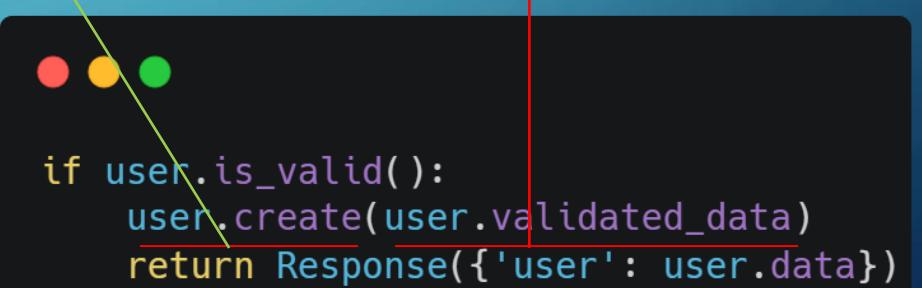

- In this session we want to use `.create` and `.update` from model serializers
- In this circumstance there is no need to create user in views ! We just use it in model serializers ! Therefore follow the below commands:
  - 1- create a function in serializer class which call it `create`
  - 2- Copy `views.py` `create` part into serializer
  - 3- call `create` in `views.py`

# .CREATE

This is the change that we do it on Views.py

Giving create method our validated data from serializer

Our serializer name + calling  
create method

```
if user.is_valid():
    user.create(user.validated_data)
    return Response({'user': user.data})
```

# .CREATE

This 2 start create connection between validated\_data and User , which means gives validated\_data information into User class

Create method

The validated data which user sent us by Request.POST

```
def create(self, validated_data):  
    return User.objects.create_user(**validated_data)
```

But we have a problem here ! User don't get password 2 from us but validated data have the password 2 field so what should we do ? → answer : we have to delete password 2 field

# .CREATE

Therefore we delete password 2 in create user but  
it's going to be validated so don't worry!

```
● ● ●  
def create(self, validated_data):  
    del validated_data['password2']  
    return User.objects.create_user(**validated_data)
```

# STATUS CODES

- Requirement : for knowing status codes you can read my article
  - <https://virgool.io/@Niklaus/http-status-codes-fo0o0tvji674>
- Now here we want to use the status codes in response method
- There is 2 way to make status codes readable :
- A. Writing manual Status code (not recommended)
- B. using rest framework to send status code

# STATUS CODE

- For sending manual status code just do like this !

```
class RegisterView(APIView):  
    def post(self, request):  
        user = UserRegisterSerializer(data = request.POST)  
        if user.is_valid():  
            user.create(user.validated_data)  
            return Response({'user': user.data})  
        return Response(user.errors, status=500)
```

# STATUS CODE

- Now by using rest framework
- A. Import status from rest\_framework
- B. Write it in response function and chose the status code that you want

```
from rest_framework import status

class RegisterView(APIView):
    def post(self, request):
        user = UserRegisterSerializer(data = request.POST)
        if user.is_valid():
            user.create(user.validated_data, status = status.HTTP_201_CREATED)
            return Response({'user': user.data})
        return Response(user.errors, status= status.HTTP_400_BAD_REQUEST)
```

Note : use the proper  
status code !

# AUTHENTICATION

- Authentication uses for identify the user for changing user access have to use changing permissions.
- When we authenticate user 2 method going to set for us
  - 1- `request.user` → which save user information
  - 2- `request.auth` → which save user authentication information

# AUTHENTICATION

- We have 3 ways to introduce authentication in our Django project
- 1- in setting.py → in this case the authentication introduce to all views, and all of the project
- 2- in views if we use CBV → in this case we introduce authentication in just one class by using authentication\_classes property
- 3- in views if we use FBV → in this case we use authentication\_classes as decorator

# UNAUTHORIZED AND FORBIDDEN

- If the user is unauthorized we have to use 401 status code
- And if it's forbidden which means permission denied we have to use 403 status code

# TYPES OF AUTHENTICATION

- 1- Basic Authentication → kind of useless ! Just for test !
- 2- Token authentication → which authenticate users by token
- 3- session authentication
- 4- Remote user authentication
- 5- third party packages:
  - JWT, Django Guardian and etc...

# TOKEN AUTHENTICATION

- For authenticating user , user send us the token !
- Many of views which we created is login required therefore we can't ask user to login again and again. Thus we use token authentication which means the browser send us the token and prove that the user is authenticated.

Now user use the token when he is connected in our server

# TOKEN AUTHENTICATION

- Step A. introduce authtoken in installapps in setting.py
- Step B. Migrate !

```
● ● ●  
#setting.py on installapps  
'rest_framework.authtoken',  
  
#on terminal  
python manage.py migrate
```

# TOKEN AUTHENTICATION

- There is some different ways to create token for users
- 1- manual
- 2- by using signals
- 3- by using for loop ! (by using get or create method)
- 4- use authtoken views
- 5- use obtainauthtoken
- 6- in Django admin
- 7- by using python manage.py
- We are going to use number 4

# BY USING VIEWS IN URLs

- Step A. import views from .authtoken as auth\_token
- Step B. Create a new url and use auth\_token to call obtain\_auth\_token

```
from django.urls import path
from . import views
from rest_framework.authtoken import views as auth_token

app_name = 'accounts'

urlpatterns = [
    path('register/', views.RegisterView.as_view(), name = 'register'),
    path('api-token-auth/', auth_token.obtain_auth_token)
]
```

# RESULT

The screenshot shows the Postman application interface with the following details:

**Request Method:** POST  
**Request URL:** http://127.0.0.1:8000/accounts/api-token-auth/

**Body (form-data):**

Key	Value
<input checked="" type="checkbox"/> username	mamamamad
<input type="checkbox"/> email	mohammad23@gmail.com
<input checked="" type="checkbox"/> password	123456456
<input type="checkbox"/> password2	123456456

**Response Body (Pretty JSON):**

```
1 {  
2     "token": "3b12710186e762d160efa0d8d7bb46b3f6092750"  
3 }
```

# DEFINE THE AUTHENTICATION

- Now we want to introduce authentication by using first way which means , define it in setting.py

The screenshot shows a code editor window with a dark theme. At the top left are three colored circular icons: red, yellow, and green. Below them is a snippet of Python code:

```
#setting.py
REST_FRAMEWORK = {
    'DEFAULT_AUTHENTICATION_CLASSES': [
        'rest_framework.authentication.TokenAuthentication',
    ]
}
```

Annotations are present in the code:

- A yellow double-headed arrow points from the text "Define the authentication" to the line `'rest_framework.authentication.TokenAuthentication'`.
- A red arrow points from the text "Our authentication type" to the same line.

Define the authentication

Our authentication type

# PERMISSIONS

- Permission with authentications and throttling can limit users access.
- If a user don't have permission he/she got 2 errors
  - 1- permission denied
  - 2- not authenticated

# DEFINING PERMISSION

- Same as authentication there is 3 ways to define permission (introduce it) into Django
  - A. by define permission\_classes in setting.py which effect all on views
  - B. by define permission\_classes in views (CBV)
  - C. by define permission\_classes as decorator (FBV)

# TYPE OF PERMISSIONS

- A. allow any: which let all users have access to this view rather user authenticated or not ( this is default permission)
- B. IsAuthenticated: if user is authenticated can have access
- C. IsAdminUser : user has to authenticate and staff (admin)
- D. IsAuthenticatedOrReadOnly: if user authenticated can POST but if user didn't authenticate just Read Only which means safe methods → HEAD, GET, OPTION
- E. Custom permission : which we can create the our designed permission

# DEFINING PERMISSION IN VIEWS

- Step A: import our method from `rest_framework.permission`
- Step B: create class variable
- Step C: give the class variable the method

The authentication method

```
#views.py
from rest_framework.permissions import IsAuthenticated
class GetName(APIView):
    permission_classes = [IsAuthenticated,]
    def get(self, request):
        ...
```

# RESULT

The screenshot shows the Postman application interface. At the top, there is a header bar with the URL `http://127.0.0.1:8000/home/getname/`. Below the header, the method is set to `GET`, and the URL is repeated in the input field. To the right of the URL are buttons for `Save`, `Send`, and other options. The main workspace has tabs for `Params`, `Authorization`, `Headers (6)`, `Body`, `Pre-request Script`, `Tests`, `Settings`, and `Cookies`. The `Params` tab is currently selected. Under `Query Params`, there is a table with columns: Key, Value, Description, and Bulk Edit. The table is empty. Below this, there is a section for `Body`, `Cookies`, `Headers (11)`, and `Test Results`. The `Body` section is active and displays a JSON response. The response is shown in Pretty, Raw, Preview, and Visualize formats. The JSON content is:

```
1 {  
2     "detail": "Authentication credentials were not provided."  
3 }
```

At the top of the body section, there are status indicators: 401 Unauthorized, 9 ms, 408 B, and a `Save as example` button.

# AUTHORIZING

- For authentication by token and read the data we have to send token in header
- So we extract our token from admin panel
- Then put it in header part with this order
- Key = authorization value : token token\_number

# RESULT

HTTP <http://127.0.0.1:8000/home/getname/>

GET <http://127.0.0.1:8000/home/getname/>

6       "email": "mmd@gmail.com"
7     },
8     {
9       "name": "mamadkevin",
10      "age": 32,
11      "email": "kevin@gmail.com"
12    }
13  ]
```

# QUESTION- ANSWER

- Want to create a view which get the question and return answer (by users)
- Step A : create new model in models.py and name it question
- Step B: create new model in models.py and name it answer
- Step C : register it on admin panel, makemigrations and migrate
- Step D : Create Serializer for it cause we want to create API
- Step E : create a class to do CRUD → (create , read, update , delete)

# STEP A

Import User model too !

Create related name for user too (questions)

```
● ● ●  
class Question(models.Model):  
    user = models.ForeignKey(User, on_delete=models.CASCADE)  
    title = models.CharField(max_length=150)  
    slug = models.SlugField(max_length = 150)  
    body = models.TextField()  
    created = models.DateTimeField(auto_now_add=True)  
  
    def __str__(self):  
        return f'{self.user} - {self.title}'
```

## STEP B

```
● ● ●  
  
class Answer(models.Model):  
    user = models.ForeignKey(User, on_delete=models.CASCADE, related_name = 'answers')  
    question = models.ForeignKey(Question, on_delete=models.CASCADE, related_name = 'answers')  
    body = models.TextField()  
    created = models.DateTimeField(auto_now_add=True)  
  
    def __str__(self):  
        return f'{self.user} - {self.question.title}'
```

## STEP C

```
#on admin.py  
admin.site.register(Question)  
admin.site.register(Answer)  
  
#on terminal  
python manage.py makemigrations  
python manage.py migrate
```

## STEP D

```
#serializer.py
class QuestionSerializer(serializers.ModelSerializer):
    class Meta:
        model = Question
        fields = '__all__'

class AnswerSerializer(serializers.ModelSerializer):
    class Meta:
        model = Answer
        fields = '__all__'
```

# STEP E

Note : we can create one view for all of operations in CRUD

R

Read method

C

Create method

U

Update method

D

Delete method

CRUD

```
class QAVView(APIView):
    def get(self, request):
        pass

    def post(self, request):
        pass

    def put (self, request, id):
        pass

    def delete(self, request, id):
        pass
```

# POST PUT DELETE

- POST → for create
- PUT → put for update
- DELETE → for delete !
- We start from POST

# POST

Sending the data to our serializer

```
def post(self, request):
    question_serializer = QuestionSerializer(data = request.POST)
    if question_serializer.is_valid():
        question_serializer.save()
        return Response(data = question_serializer.data , status= status.HTTP_201_CREATED)
    return Response(question_serializer.errors, status= status.HTTP_400_BAD_REQUEST)
```

# RESULT

But I create before taking screenshot! My bad 😊

The screenshot shows a Postman interface for a POST request to `http://127.0.0.1:8000/questions/`. The request has 9 Headers and a JSON Body. The Body contains four fields: title, slug, body, and user, all set to "second2". The response is a 200 OK status with a timestamp of 2024-02-14T07:54:40.611985Z and an id of 2. A second entry with id 3 is also present.

Key	Value	Description
title	Text: second2	
slug	Text: second2	
body	Text: this is second2	
user	Text: 2	

Key	Value	Description

```
11 |     "id": 2,
12 |     "title": "second",
13 |     "slug": "second",
14 |     "body": "this is second",
15 |     "created": "2024-02-14T07:54:40.611985Z",
16 |     "user": 2
17 },
18 {
19 |     "id": 3,
20 |     "title": "second",
21 |     "slug": "second",
22 |     "body": "this is second",
23 |     "created": "2024-02-14T07:57:43.198269Z",
```

# PUT

- Here we have different task !
- Attention: for updating a question we have to get the id from database
  - But there is no id in urls ! So we need to create 2 urls with same view

```
path('questions/', views.QAView.as_view(), name = 'questions'),
path('questions/<int:id>', views.QAView.as_view(), name = 'questionsid'),
```

# PUT

Partial true means may update one field not the all fields

Giving the question information to serializer

That's why we needs 2 urls

```
● ● ●  
def put (self, request, id):  
    question = Question.objects.get(id = id)  
    question_serializer = QuestionSerializer(instance= question, data = request.POST, partial = True)  
    if question_serializer.is_valid():  
        question_serializer.save()  
        return Response(question_serializer.data, status= status.HTTP_200_OK)  
    return Response(question_serializer.errors, status= status.HTTP_400_BAD_REQUEST)
```

# DELETE

Everything is clear !

```
def delete(self, request, id):
    question = Question.objects.get(id = id)
    question.delete()
    return Response({'message': 'question deleted'}, status= status.HTTP_200_OK)
```

# METHOD FIELD

- Now we want to separate our method in different classes and then we want to show the answers through the questions.
- In documentation we are going to use miscellaneous fields which is very useful!
- In miscellaneous fields we have a part which call it serializer method field which let you connect a serializer field to method and whatever you return on that method will connect to that field

# METHOD FIELD

Because we are in  
QuestionSerializer , obj are  
all questions that user can  
read

Using related name in  
our models

Create a field to connect it to method

```
class QuestionSerializer(serializers.ModelSerializer):
    answers = serializers.SerializerMethodField

    class Meta:
        model = Question
        fields = '__all__'

    def answers_all(self, obj):
        result = obj.answers.all()
        return AnswerSerializer(instance=result, many=True).data
```

Cause we got all answers by using  
related name now we can call answer  
serialzier

# HOW TO USE METHOD FIELD?

- 2 Ways
  - A. use signature , give the field the method name
  - B. use `get_field`
- We are going to use method B

# USING METHOD FIELDS

I changed my method name to  
get\_<field\_name> therefore automatically this  
method sends data to my field

Thus we connect a field to method

Forgot the  
parentheses

```
class QuestionSerializer(serializers.ModelSerializer):
    answers = serializers.SerializerMethodField

    class Meta:
        model = Question
        fields = '__all__'

    def get_answers(self, obj):
        result = obj.answers.all()
        return AnswerSerializer(instance= result, many = True).data
```

# RESULT

The screenshot shows the Postman application interface. At the top, the URL `http://127.0.0.1:8000/questions/` is entered into the address bar, and the method is set to `GET`. Below the address bar, there are tabs for `Params`, `Authorization`, `Headers (7)`, `Body`, `Pre-request Script`, `Tests`, and `Settings`. The `Params` tab is currently selected. In the `Query Params` section, there is a table with columns `Key`, `Value`, `Description`, and `... Bulk Edit`. The table is currently empty. Below the table, there are tabs for `Body`, `Cookies`, `Headers (10)`, and `Test Results`. The `Body` tab is selected. The response body is displayed in a JSON editor with the following content:

```
3 |   "id": 1,
4 |   "answers": [
5 |     {
6 |       "id": 1,
7 |       "body": "this is answer 1",
8 |       "created": "2024-02-14T07:52:17.359688Z",
9 |       "user": 1,
10 |       "question": 1
11 |     }
12 |   ],
13 |   "title": "hi this is question 1",
14 |   "slug": "hi-this-is-question-1",
15 |   "body": "this is the body of question 1",
16 |   "created": "2024-02-14T07:52:04.616635Z",
17 |   "user": 4
18 |
19 | }
```

At the bottom of the JSON editor, there are buttons for `Pretty`, `Raw`, `Preview`, `Visualize`, and `JSON`. To the right of the JSON editor, there are status indicators: `200 OK`, `17 ms`, `963 B`, and a `Save as example` button.

# SEPARATING VIEWS

- Now we want to separating our views (because in future may we have problem with permissions or etc... )

```
class QuestionReadView(APIView):
    def get(self, request):
        question = Question.objects.all()
        question_serializer = QuestionSerializer(instance= question , many = True)
        return Response(question_serializer.data, status= status.HTTP_200_OK)

class QusetionCreateView(APIView):
    def post(self, request):
        question_serializer = QuestionSerializer(data = request.POST)
        if question_serializer.is_valid():
            question_serializer.save()
            return Response(data = question_serializer.data , status= status.HTTP_201_CREATED)
        return Response(question_serializer.errors, status= status.HTTP_400_BAD_REQUEST)

class QuestionUpdateView(APIView):
    def put (self, request, id):
        question = Question.objects.get(id = id)
        question_serializer = QuestionSerializer(instance= question, data = request.POST, partial = True)
        if question_serializer.is_valid():
            question_serializer.save()
            return Response(question_serializer.data, status= status.HTTP_200_OK)
        return Response(question_serializer.errors, status= status.HTTP_400_BAD_REQUEST)

class QuestionDeleteView(APIView):
    def delete(self, request, id):
        question = Question.objects.get(id = id)
        question.delete()
        return Response({'message': 'question deleted'}, status= status.HTTP_200_OK)
```

# CUSTOM PERMISSION

- Sometimes we need to create a permission ! That's why we use **custom permission**
- For creating **custom permission** we have to create a class which in heritage from **BasePermission** on that class we can have 2 methods :
  - `Has_permission(self, request, view)` → which check that user can come into the view or not
  - `Has_object_permission(self, request, view, obj)` → which check that if user come into the view can change anything or not

# CUSTOM PERMISSION

- `Has_permission(self, request, view)` → before user come into view
- `Has_object_permission(self, request, view, obj)` → after user come into view

# REMINDER

- As you remember we had a `permission_classes[]` now we have to use it here on our views on POST PUT DELETE view.

```
class QuestionUpdateView(APIView):
    permission_classes = [IsAuthenticated,]
    def put (self, request, id):
        question = Question.objects.get(id = id)
        question_serializer = QuestionSerializer(instance= question, data = request.POST, partial = True)
        if question_serializer.is_valid():
            question_serializer.save()
            return Response(question_serializer.data, status= status.HTTP_200_OK)
        return Response(question_serializer.errors, status= status.HTTP_400_BAD_REQUEST)
```

But There is one problem!

# PROBLEM

- The problem is the authenticated user can change every question not just his mine therefore we have to use custom permission.
- Therefore we have to create a permission which just allow the owner (author) of question to let change the question

# CREATE CUSTOM PERMISSION

- Step A : create a file which call it permissions in base DIR
- Step B : from rest\_freamwork.permission import BasePermission
- Step C : Craete a class which inheritance from BasePermission
- Step D : If you remember we had 2 methods for basepermission in this place user authenticated thus he have access to view so we need the second method

# CREATE CUSTOM PERMISSION

The object that we want to change it  
in our example object is our question

```
from rest_framework.permissions import BasePermission

class ChangeOrReadOnly(BasePermission):
    def has_object_permission(self, request, view, obj):
        pass
```

# SAFE METHODS

- Safe methods are the method which they are safe !
  - Safe methods are : HEAD , OPTION , GET
- Now we have to check if it is safe method or not

```
from rest_framework.permissions import BasePermission,SAFE_METHODS

class ChangeOrReadOnly(BasePermission):

    def has_object_permission(self, request, view, obj):
        if request.method in SAFE_METHODS:
            return True
        return obj.user == request.user
```

This is our question class

# USING CUSTOM PERMISSION

- Step A: I have to import it on my views
- Step B : I have to define it permission\_classes
- Step C: I have to use check\_object\_permission
- Step A+ : also we can override a message

```
class ChangeOrReadOnly(BasePermission):  
    message = 'You are not the author'  
  
    def has_object_permission(self, request, view, obj):  
        if request.method in SAFE_METHODS:  
            return True  
        return obj.user == request.user
```

# USING CUSTOM PERMISSION

```
● ● ●  
#step A  
from permission import ChangeOrReadOnly  
#step B  
class QuestionUpdateView(APIView):  
    permission_classes = [IsAuthenticated, ChangeOrReadOnly]
```

But It won't work because APIView class don't check the permission automatically therefore we need to use a method which call it `check_object_permission(request, obj)`

# USING CUSTOM PERMISSION

- STEP C:

```
● ● ●  
class QuestionUpdateView(APIView):  
    permission_classes = [IsAuthenticated, ChangeOrReadOnly]  
    def put (self, request, id):  
        question = Question.objects.get(id = id)  
        self.check_object_permissions(request, question)
```

This method make the APIView to check  
the custom permissions

This our obj (in permission class and here this is our  
obj that we want to give it a permission)

# CUSTOM PERMISSION

- Also we can create IsAuthenticated in custom permission

```
● ● ●  
class ChangeOrReadOnly(BasePermission):  
    message = 'You are not the author'  
  
    def has_permission(self, request, view):  
        return request.user.is_authenticated and request.user  
  
    def has_object_permission(self, request, view, obj):  
        if request.method in SAFE_METHODS:  
            return True  
        return obj.user == request.user
```

User has not be a None

Then give this permission to  
view (PUT and delete).

# SERIALIZER RELATIONS

- Serializer relations define that how we can show the relation in a result

This User is author of question  
We create it on model.py  
It return us the primary key which is id  
Now we want to change it to email , username or etc

```
1  {
2   "id": 1,
3   "answers": [
4     {
5       "id": 1,
6       "body": "this is answer 1",
7       "created": "2024-02-14T07:52:17.359688Z",
8       "user": 1,
9       "question": 1
10      }
11    ],
12    "title": "hi this is question 1",
13    "slug": "hi-this-is-question-1",
14    "body": "this is the body of question 1",
15    "created": "2024-02-14T07:52:04.616635Z",
16    "user": 4
17  },
18}
```

# TYPES OF SERIALIZER RELATION

- 1- string related field → which return us everything in `__str__` ( we used User class for authentication this class return username in `__str__`) therefore it shows us username
- 2- primary key related field → which return us primary key (the default behavior is like that) [ this is just like string field don't need to learn]
- 3- hyper link related field → which return us a specific url
- 4- slug related field → which we can chose what field do we want
- 5- custom relational field → it's custom !

# STRING RELATED FIELD

Read only on  
true which limit  
the user access ,  
and user can't  
change the  
relation

```
class QuestionSerializer(serializers.ModelSerializer):
    answers = serializers.SerializerMethodField()
    user = serializers.StringRelatedField(read_only = True)

    class Meta:
        model = Question
        fields = '__all__'
```

# SLUG FIELD

Which I say that to shows email from user informations

```
class QuestionSerializer(serializers.ModelSerializer):
    answers = serializers.SerializerMethodField()
    user = serializers.SlugRelatedField(read_only = True , slug_field='email')

    class Meta:
        model = Question
        fields = '__all__'
```

# CUSTOM RELATION FIELD

- Step A : in your app create a .py file (u can name it as u want)
- Step B: import serializer
- Step C: inheritance .relationfield
- Step D: to \_reperensetive method

# CRF

In crf.py file , value is our User model

```
● ● ●  
from rest_framework import serializers  
  
class UserNameEmailRelationField(serializers.RelatedField):  
    def to_representation(self, value):  
        return f'{value.username} - {value.email}'
```

# USE IT IN SERIALIZER

```
● ● ●  
from .crf import UserNameEmailRelationField  
  
class QuestionSerializer(serializers.ModelSerializer):  
    answers = serializers.SerializerMethodField()  
    user = UserNameEmailRelationField(read_only = True)  
  
    class Meta:  
        model = Question  
        fields = '__all__'
```

# VIEWSETS

- Viewsets allows us to put many operation (process) in one class
- For each class we create a url but when project develop so much and get bigger it's gonna be difficult, Thus we use Viewsets
- Viewset allow us to do 5-6 process in 1 class therefore we need 1 urls for 5-6 process
- Viewset is a type from CBV but it doesn't have .get , .post and etc... instead provides process as method like .list , .create and etc...

# VIEWSETS

- Each viewset has 6 actions
  - 1- list : for listing all data`s (reading all data`s)
  - 2- create: for creating new object
  - 3- retrieve: for reading 1 object
  - 4- update : for updating an object but if it doesn`t exist update create it for us
  - 5-partial\_update : for updating a part of object
  - 6-destroy : for deleteing

# VIEWSETS

- Now we want to use viewset in accounts app for managing users
  - A. classes have to in heritage from viewset.viewset
  - B. we have to import viewset !

```
● ● ●  
from rest_framework import viewsets  
  
class UserViewSet(viewsets.ViewSet):  
    pass
```

# WHEN WE USE VIEWSET

- We use viewset when code is not complicated. If it's complicated use APIVIEW

For show all user

For show 1 user

For update a part of user data

For delete user

```
class UserViewSet(viewsets.ViewSet):  
    def list(self, request):  
        pass  
  
    def retrieve(self, request, pk = None):  
        pass  
  
    def partial_update(self, request, pk = None):  
        pass  
  
    def destroy(self, request, pk = None):  
        pass
```

# WHY DO WE USE VIEWSETS?

- 2 reason
  - A. can put many methods on 1 class
  - B. using routers that makes need less to urls
- Negative point:
  - Some views created by routers automatically which make the program hard to read

# CREATE A VIEWSET

- For creating viewset
  - 1- create a serializer for it
  - 2- set the permission you want (I set IsAuthenticated)
  - 3- create the list view

# CREATE SERIALIZER FOR VIEWSET

```
● ● ●  
class UserSerializer(serializers.ModelSerializer):  
    class Meta:  
        model = User  
        fields = '__all__'
```

I think everything is clear !

# CREATE VIEWSET

I create a class variable from User class cause it's going to repeat many times

Creating a variable and giving that our serialzier which using our queryset(User class instance)

```
● ● ●  
from .serializers import UserRegisterSerializer, UserSerializer  
from rest_framework.permissions import IsAuthenticated  
from django.contrib.auth.models import User  
  
class UserViewSet(viewsets.ViewSet):  
    permission_classes = [IsAuthenticated,]  
    queryset = User.objects.all()  
  
    def list(self, request):  
        user_serializer = UserSerializer(instance= self.queryset, many = True)  
        return Response(data = user_serializer.data)
```

# CREATE URL FOR VIEWSET

- Default urls can't connect to viewset cause viewsets has different methods
- For viewset we use routers
- Routers create url automatically for us and suitable for viewsets

# HOW ROUTERS CREATE URL ?

URL Style	HTTP Method	Action	URL Name
{prefix}/	GET	list	{basename}-list
	POST	create	
{prefix}/{url_path}/	GET, or as specified by `methods` argument	`@action(detail=False)` decorated method	{basename}-{url_name}
{prefix}/{lookup}/	GET	retrieve	{basename}-detail
	PUT	update	
	PATCH	partial_update	
	DELETE	destroy	
{prefix}/{lookup}/{url_path}/	GET, or as specified by `methods` argument	`@action(detail=True)` decorated method	{basename}-{url_name}

Lookup means primary key

# CREATE ROUTERS

- A. import routers
- B. create instance from simple router
- E. generate urls by the instance

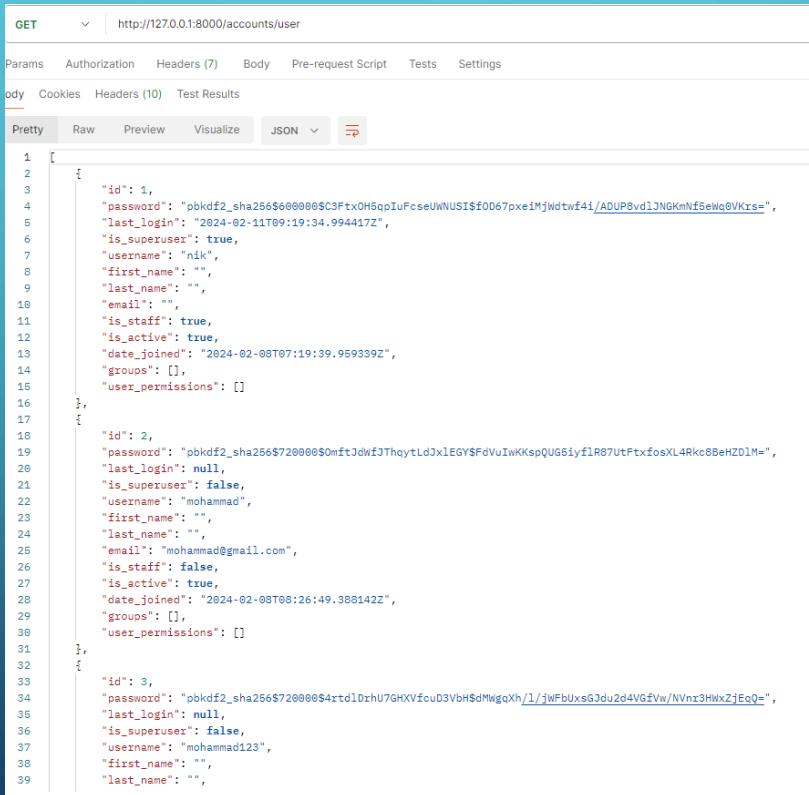

Create instance and give it the url + our viewset

Add it to urls patterns our urls from router

```
● ● ●  
from django.urls import path  
from . import views  
from rest_framework.authtoken import views as auth_token  
from rest_framework import routers  
  
app_name = 'accounts'  
  
urlpatterns = [  
    path('register/', views.RegisterView.as_view(), name = 'register'),  
    path('api-token-auth/', auth_token.obtain_auth_token)  
]  
  
router = routers.SimpleRouter()  
router.register('user', views.UserViewSet)  
  
urlpatterns += router.urls
```

# ROUTERS

- Now according to slide 117<sup>th</sup> if we call our path by GET method it has to show us our member

The screenshot shows a Postman request for `http://127.0.0.1:8000/accounts/user` using the GET method. The response body is displayed in JSON format, showing three user objects:

```
1 [  
2   {  
3     "id": 1,  
4     "password": "pbkdf2_sha256$60000$C3FtxOH5qpIuFcseUWNUSI$0d67pxeiMjWdtwf4i/ADUPBvd1JNGKmNf5eWq@Vkrss=",  
5     "last_login": "2024-02-11T09:19:34.994417Z",  
6     "is_superuser": true,  
7     "username": "nik",  
8     "first_name": "",  
9     "last_name": "",  
10    "email": "",  
11    "is_staff": true,  
12    "is_active": true,  
13    "date_joined": "2024-02-08T07:19:39.959339Z",  
14    "groups": [],  
15    "user_permissions": []  
16  },  
17  {  
18    "id": 2,  
19    "password": "pbkdf2_sha256$72000$0mtfJdwfJThaytLdJxLEGY$FdVuIwKKspQUG6iyflR87UtFtxfosXL4Rkc8BeHZDlM=",  
20    "last_login": null,  
21    "is_superuser": false,  
22    "username": "mohammad",  
23    "first_name": "",  
24    "last_name": "",  
25    "email": "mohammad@gmail.com",  
26    "is_staff": false,  
27    "is_active": true,  
28    "date_joined": "2024-02-08T08:26:49.388142Z",  
29    "groups": [],  
30    "user_permissions": []  
31  },  
32  {  
33    "id": 3,  
34    "password": "pbkdf2_sha256$72000$4rtdlDrhu76HXVfcu03Vbh$0MwgqXh/l/jWFbUxsGJdu2d4VGEvw/NVnx3HwXZjEoQz",  
35    "last_login": null,  
36    "is_superuser": false,  
37    "username": "mohammad123",  
38    "first_name": "",  
39    "last_name": ""  
]
```

# CREATE MORE VIEWSETS

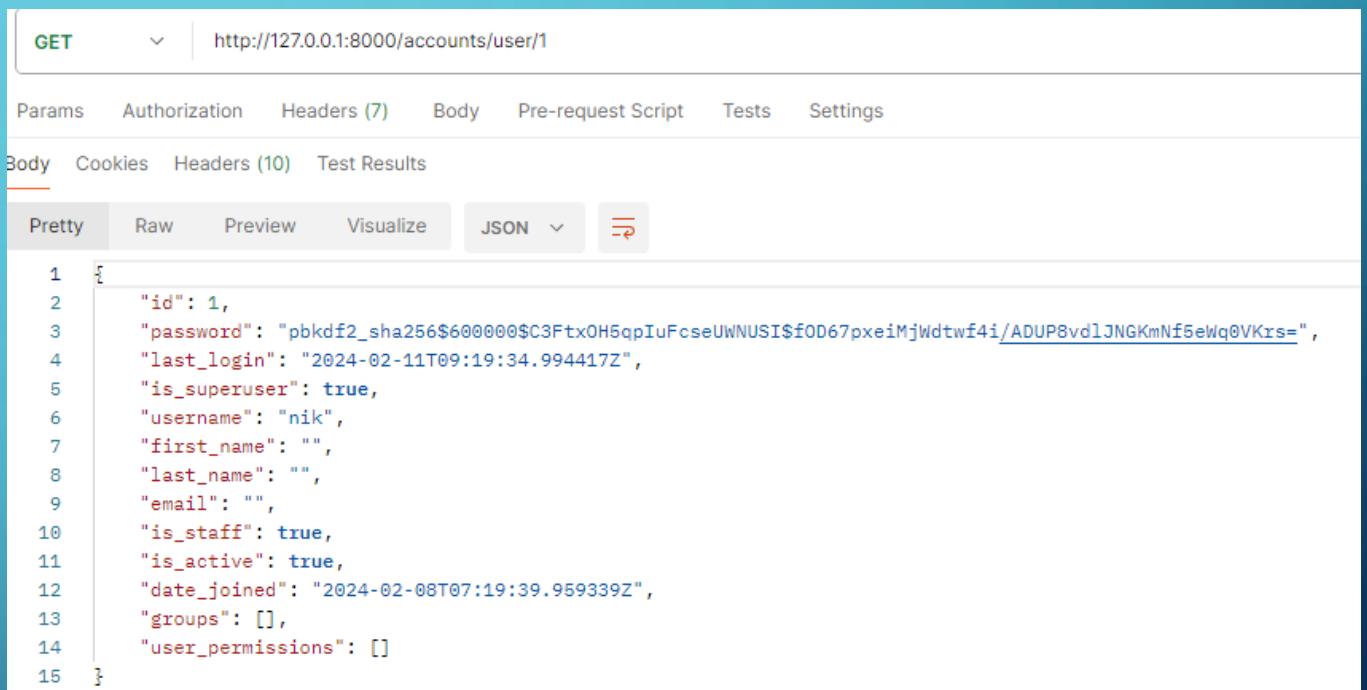

I had queryset and it was all of my users but I didn't need all therefore I filter it by pk

```
from django.shortcuts import get_object_or_404

def retrieve(self, request, pk = None):
    user = get_object_or_404(self.queryset, pk = pk)
    user_serializer = UserSerializer(instance = user )
    return Response(data = user_serializer.data)
```

# RESULT

According to table at 117<sup>th</sup> slide if we user prefix + lookup the retrieve method is going to activate and we don't need to create specific url for it

GET http://127.0.0.1:8000/accounts/user/1

Params Authorization Headers (7) Body Pre-request Script Tests Settings

Body Cookies Headers (10) Test Results

Pretty Raw Preview Visualize JSON ↻

```
1 {  
2     "id": 1,  
3     "password": "pbkdf2_sha256$600000$C3Ftx0H5qpIuFcseUWNUSI$f0D67pxeiMjWdtwf4i/ADUP8vd1JNGKmNf5eWq0VKrs=",  
4     "last_login": "2024-02-11T09:19:34.994417Z",  
5     "is_superuser": true,  
6     "username": "nik",  
7     "first_name": "",  
8     "last_name": "",  
9     "email": "",  
10    "is_staff": true,  
11    "is_active": true,  
12    "date_joined": "2024-02-08T07:19:39.959339Z",  
13    "groups": [],  
14    "user_permissions": []  
15 }
```

# PARTIAL\_UPDATE VIEWSET

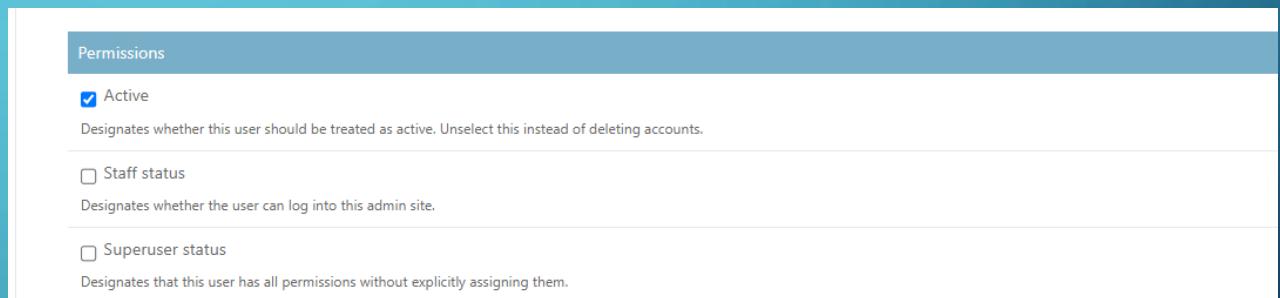

```
def partial_update(self, request, pk = None):
    user = get_object_or_404(self.queryset, pk = pk)
    user_serializer = UserSerializer(instance = user, data = request.POST , partial = True)
    if user_serializer.is_valid():
        user_serializer.save()
        return Response(data = user_serializer.data)
    return Response(user_serializer.errors)
```

I give it user as instance I tell my serializer that  
user want to send data

# DESTROY USER VIEWSET

- In real world ! We don't delete the user just deactivate it

On admin panel

Using code

```
def destroy(self, request, pk = None):
    user = get_object_or_404(self queryset, pk = pk)
    user.is_active = False
    user.save()
    return Response({'message': 'user deactivated'})
```

A code block showing a Python function named `destroy`. The function takes `self`, `request`, and `pk` as parameters. It uses `get_object_or_404` to retrieve a user object. Then it sets `user.is_active` to `False`, saves the changes, and returns a response with the message "user deactivated".

# USING CUSTOM PERMISSION ON VIEWSET

- It's different a little bit for performance there is no `has_object_permission()` on viewsets
- If we want to use custom permission we have to use `perform_create()` or validate it by serializers
- (it's a simple if !)

```
if request.user != user:  
    return Response({'message': 'you are not the owner'})
```

# THROTTLING

- Throttling just like permission but the different is throttling is using for limitation in sending request by user for example each user can send 100 request in 1 hour or the users who didn't authenticate can send 10 request in 1 hour
- Note : don't use throttling for security isn't enough if you want to handle brute force or denial of service throttling isn't good enough because hackers can change their ip and ditch throttling

# THROTTLING

- Throttling using `x_forwarded_for` Http header and `REMOTE_ADDR` for identify users if user change those 2 throttling will not know the user . Usually professional users or hackers just change that

# SETTING THE THROTTLING POLICY

- A. by using setting which effect on all views
- B. by using class variable in CBV
- C. by using decorators in FBV
- Note : we have to define the request per day/hour/minute/second

# DEFINE THROTTLING IN SETTING

Where we define rest frame work we define throttling too

For anonymous users

For authenticated users

Define it the anon and user how much request can send in 1 hour

```
#rest framework
REST_FRAMEWORK = {
    'DEFAULT_AUTHENTICATION_CLASSES': [
        'rest_framework.authentication.TokenAuthentication',
    ],
    'DEFAULT_THROTTLE_CLASSES' : [
        'rest_framework.throttling.AnonRateThrottle',
        'rest_framework.throttling.UserRateThrottle'
    ],
    'DEFAULT_THROTTLE_RATES' : {
        'anon' : '3/hour',
        'user' : '10/hour'
    }
}
```

DEFAULT\_THROTTLE\_CLASSES is a list

DEFAULT\_THROTTLE\_RATES is a dictionary

# DEFINE THROTTLING IN CLASSES

- A. Delete this part
- B. But don't touch  
THROTTLE RATES

```
#rest_framework
REST_FRAMEWORK = {
    'DEFAULT_AUTHENTICATION_CLASSES': [
        'rest_framework.authentication.TokenAuthentication',
    ],
    'DEFAULT_THROTTLE_CLASSES' : [
        'rest_framework.throttling.AnonRateThrottle',
        'rest_framework.throttling.UserRateThrottle'
    ],
    'DEFAULT_THROTTLE_RATES' : {
        'anon' : '3/hour',
        'user' : '10/hour'
    }
}
```

```
from rest_framework.throttling import UserRateThrottle, AnonRateThrottle
class QuestionReadView(APIView):
    throttle_classes = [UserRateThrottle, AnonRateThrottle]

    def get(self, request):
        question = Question.objects.all()
        question_serializer = QuestionSerializer(instance=question , many = |
True)
        return Response(question_serializer.data, status= status.HTTP_200_OK)
```

# SCOPED RATE THROTTLE

- Allow us to name the limitation and create the limitation by that name
- A. have to define it in setting.py
- B. use throttle scope as class variable

This is my limitation and I can use it now as class variable

```
REST_FRAMEWORK = {  
    'DEFAULT_AUTHENTICATION_CLASSES': [  
        'rest_framework.authentication.TokenAuthentication',  
    ],  
    'DEFAULT_THROTTLE_CLASSES' : [  
        'rest_framework.throttling.ScopedRateThrottle'  
    ],  
    'DEFAULT_THROTTLE_RATES' : {  
        'question' : '5/minutes'  
    }  
}
```

# USE IT SCOPED RATED THROTTLE IN CLASS

In using scoped anon or authenticated user is no different .

```
class QuestionReadView(APIView):
    throttle_scope = 'question'

    def get(self, request):
        question = Question.objects.all()
        question_serializer = QuestionSerializer(instance=question, many =
True)
        return Response(question_serializer.data, status= status.HTTP_200_OK)
```

# JWT

- Till now we were using token for authentication but there is new standard which call it JWT is stand for of JSON Web Token Authentication
- What's different ?
  - A. the token has expire and should refresh it
  - B. we don't save tokens in database instead save it on local storage of user browser
  - C. better performance of website
- The recommended method is using simple JWT

# JWT TOKEN

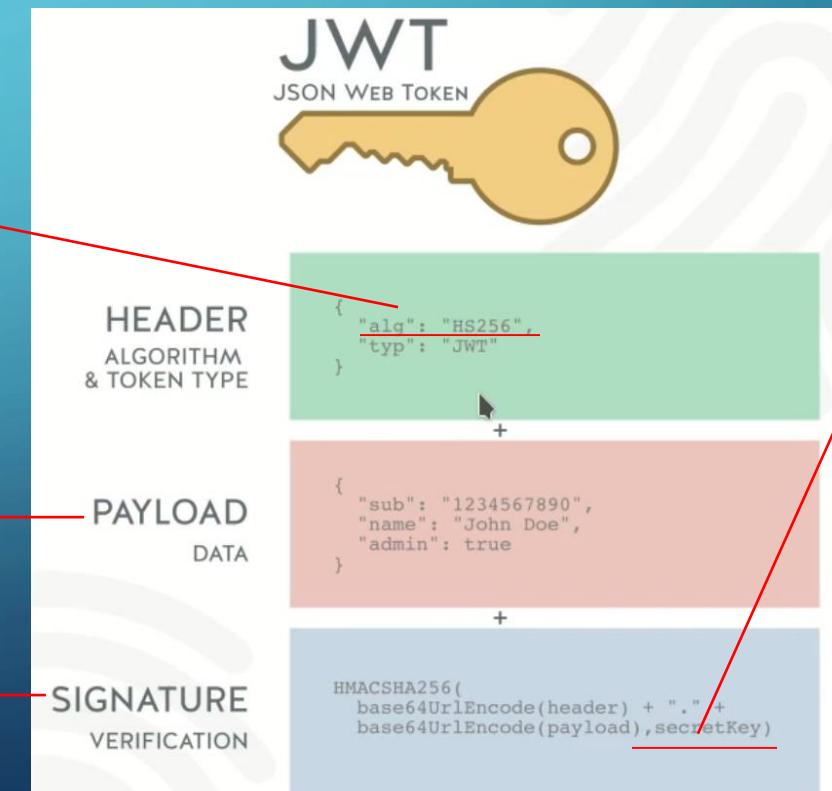

JWT Token dived in 3 part and separate by DOT (.)  
Each part doing has specific function

```
eyJhbGciOiJIUzI1NiIsInR5cCI6IkpXVCJ9.  
eyJzdWIiOiIxMjM0NTY3ODkwIiwibmFtZSI6IkpvaG4  
gRG9lIiwiaXNb2NpYWwiOnRydWV9.  
4pcPyMD09o1PSyXnrXCjTwXyr4BsezdI1AVTmud2fu4
```

Using hash 256 for header and algorithm

DATA !

For combination data

Secret  
key  
is  
available  
in  
setting.py

# JWT TOKEN

Another example.

# USING SIMPLE JWT

- A. pip install djangorestframework-simplejwt
- B. add it to setting.py in DEFAULT\_AUTHENTICATION\_CLASSES

- C. add views to urls.py

- It can be root urls.py or apps urls.py

- D. add the urls and views

- Into urlpatterns , Note : we don't need the old url for token authentication therefore delete it ! And delete it rest\_framework\_auth in setting.py

```
REST_FRAMEWORK = {
    'DEFAULT_AUTHENTICATION_CLASSES': [
        'rest_framework_simplejwt.authentication.JWTAuthentication',
    ],
```

```
from rest_framework_simplejwt.views import TokenObtainPairView, TokenRefreshView
```

```
urlpatterns = [
    path('register/', views.RegisterView.as_view(), name = 'register'),
    path('token/', TokenObtainPairView.as_view(), name = 'token_obtain_pair'),
    path('token/refresh', TokenRefreshView.as_view(), name = 'token_refresh')
]
```

# SETTING OF JWT

Access token exp  
And refresh token exp  
These two are important

Using Bearer instead of token in sending request

## Settings

Some of Simple JWT's behavior can be customized through settings variables in [settings.py](#):

```
# Django project settings.py

from datetime import timedelta
...

SIMPLE_JWT = {
    "ACCESS_TOKEN_LIFETIME": timedelta(minutes=5),
    "REFRESH_TOKEN_LIFETIME": timedelta(days=1),
    "ROTATE_REFRESH_TOKENS": False,
    "BLACKLIST_AFTER_ROTATION": False,
    "UPDATE_LAST_LOGIN": False,

    "ALGORITHM": "HS256",
    "SIGNING_KEY": settings.SECRET_KEY,
    "VERIFYING_KEY": "",
    "AUDIENCE": None,
    "ISSUER": None,
    "JSON_ENCODER": None,
    "JWK_URL": None,
    "LEEWAY": 0,

    "AUTH_HEADER_TYPES": ("Bearer",),
    "AUTH_HEADER_NAME": "HTTP_AUTHORIZATION",
    "USER_ID_FIELD": "id",
    "USER_ID_CLAIM": "user_id",
    "USER_AUTHENTICATION_RULE": "rest_framework_simplejwt.authentication.default_user_authentication_rule",

    "AUTH_TOKEN_CLASSES": ("rest_framework_simplejwt.tokens.AccessToken",),
    "TOKEN_TYPE_CLAIM": "token_type",
    "TOKEN_USER_CLASS": "rest_framework_simplejwt.models.TokenUser",

    "JTI_CLAIM": "jti",

    "SLIDING_TOKEN_REFRESH_EXP_CLAIM": "refresh_exp",
    "SLIDING_TOKEN_LIFETIME": timedelta(minutes=5),
    "SLIDING_TOKEN_REFRESH_LIFETIME": timedelta(days=1),

    "TOKEN_OBTAIN_SERIALIZER": "rest_framework_simplejwt.serializers.TokenObtainPairSerializer",
    "TOKEN_REFRESH_SERIALIZER": "rest_framework_simplejwt.serializers.TokenRefreshSerializer",
    "TOKEN_VERIFY_SERIALIZER": "rest_framework_simplejwt.serializers.TokenVerifySerializer",
    "TOKEN_BLACKLIST_SERIALIZER": "rest_framework_simplejwt.serializers.TokenBlacklistSerializer",
    "SLIDING_TOKEN_OBTAIN_SERIALIZER": "rest_framework_simplejwt.serializers.TokenObtainSlidingSerializer",
    "SLIDING_TOKEN_REFRESH_SERIALIZER": "rest_framework_simplejwt.serializers.TokenRefreshSlidingSerializer"
}
```

# USING JWT

Give us 2 token  
Refresh and access

HTTP <http://127.0.0.1:8000/accounts/token/>

POST <http://127.0.0.1:8000/accounts/token/>

Params Authorization Headers (9) **Body** Pre-request Script Tests Settings Cookies

Body (Pretty, Raw, Preview, Visualize, JSON)

Key	Value	Description
username	nik	
password	123	
		Description

Body (Pretty, Raw, Preview, Visualize, JSON)

```
1 {  
2   "refresh": "eyJhbGciOiJIUzI1NiIsInR5cCI6IkpXVCJ9.  
eyJob2t1b190eXB1jioicmVmcmVzaC1sImV4cCI6MTcwODM2ODkxOCwiaWF0IjoxNzA4MjgyNTE4LCJqdGkiOiI2YjM2Y2ZjMThjNTQ0NjUxODdkZD150TljMDZhYzU1MCisInVzZXJfaWQiOjF9.C8thtiNowUIkTPKp6gxvzTxrkv2b0AM2cpJA-eGCBJ9.",  
3   "access": "eyJhbGciOiJIUzI1NiIsInR5cCI6IkpXVCJ9.  
eyJob2t1b190eXB1jioiYWNjZXNzIiwidXhwIjoxNzA4MjgyODE4LCJpYXQiOjE3MDgyODI1MTgsImp0aSI6ImQuYWQ5NzExODFjNTQ1NDQ50DEwMjQ0MTQ1ZjM0NTcwIiwidXNlcl9pZCI6MX0.eeLHgL-T0w1F5CyK_A7hYbxNNKSOXF2SmNIvQGhzW8A"  
4 }
```

When access token expires we use refresh token  
For access to limit part we have to send access token  
Now we want to use in GetNameView in home app

# USING JWT

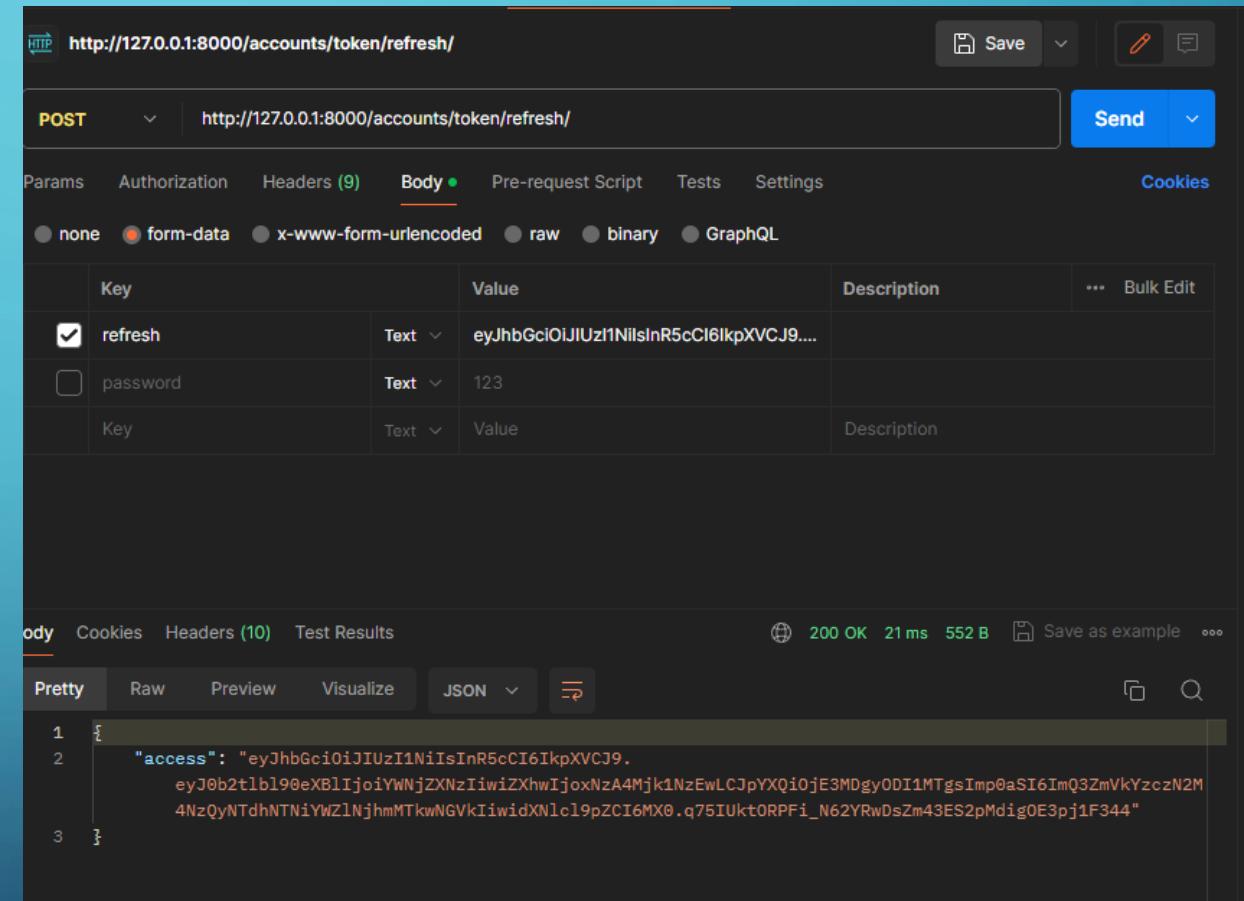

My token is expired but this is how this authentication works

The screenshot shows a Postman API request configuration and its response. The request is a GET to `http://127.0.0.1:8000/home/getname`. In the Headers tab, there is a single header named `Authorization` with the value `Bearer eyJhbGciOiJIUzI1NiIsInR5cCI6Ikp...`. The response status is 401 Unauthorized, with a response time of 37 ms and a body size of 547 B. The response body is a JSON object:

```
1 "detail": "Given token not valid for any token type",
2 "code": "token_not_valid",
3 "messages": [
4   {
5     "token_class": "AccessToken",
6     "token_type": "access",
7     "message": "Token is invalid or expired"
8   }
9 ]
10
11 ]
```

# REFRESH JWT TOKEN

I create a key which call it refresh then by POST method I connect to my refresh url then I send my refresh token for it

The screenshot shows a Postman interface for a POST request to `http://127.0.0.1:8000/accounts/token/refresh/`. The 'Body' tab is selected, showing a form-data structure:

Key	Value	Description
refresh	eyJhbGciOiJIUzI1NiIsInR5cCI6IkpXVCJ9....	
password	123	

The response tab shows a 200 OK status with a response body containing a JSON object with an 'access' key:

```
Pretty
1 {
2   "access": "eyJhbGciOiJIUzI1NiIsInR5cCI6IkpXVCJ9...."
3 }
```

Raw
eyJhbGciOiJIUzI1NiIsInR5cCI6IkpXVCJ9....

Visualize

JSON

200 OK 21 ms 552 B Save as example

# RESULT

Now I can see the data till next 5 minutes

The screenshot shows the Postman application interface. At the top, the URL is set to `http://127.0.0.1:8000/home/getname/`. Below the URL, there are tabs for Params, Authorization, Headers (7), Body, Pre-request Script, Tests, and Settings. The Headers tab is selected, showing one header named "Authorization" with the value "Bearer eyJhbGciOiJIUzI1NiIsInR5cCI6Ikp...". The Body tab is also visible at the bottom. The response section shows a status of 200 OK, 11 ms, and 431 B. The response body is displayed in Pretty format:

```
1 {  
2   "data": [  
3     {  
4       "name": "mmd",  
5       "age": 23,  
6       "email": "mmd@gmail.com"  
7     },  
8     {  
9       "name": "mamadkevin",  
10      "age": 32,  
11      "email": "kevin@gmail.com"  
12    ]  
13 }  
14 }
```

# SWAGGER

- Now we want to create a document from our API because people doesn't have enough time to read our source code
- For create a document we have to use schema , so what schema ?
- According to Django rest framework documentation :
- *A machine-readable [schema] describes what resources are available via the API, what their URLs are, how they are represented and what operations they support.*

# SCHEMA

- Schema as we told is machine readable which means human can't use it !
- Therefore we have to use some tools to turn this schema to a graphical suitable document
- First we want to create schema
  - A. pip install pyyaml → is used to generate schema into YAML-based
  - B. pip install uritemplate → for identify the urls

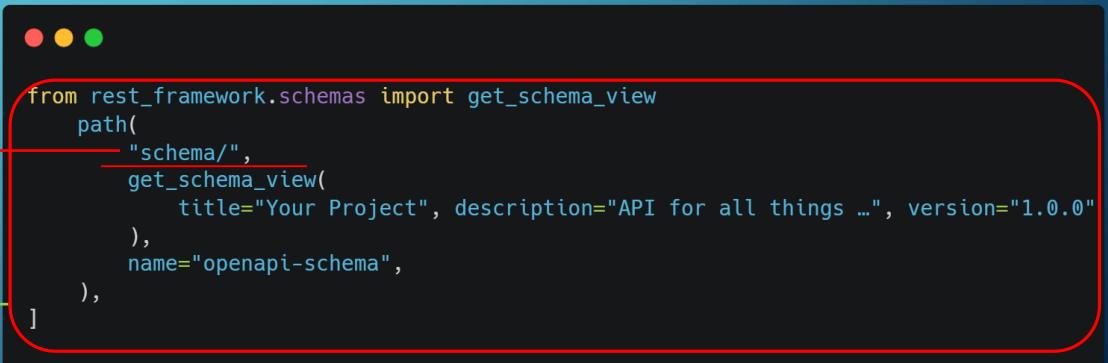

# CREATE SCHEMA

- Import `get_schema_view` and set it into main `urls.py`
- Give it the documentation path → you have to copy paste it from documentation

I changed path to schema

You have to just copy  
paste it

Now if you read the result you can see the data's are YAML based but it's hard to read  
Therefore we want to use swagger to make it readable

```
from rest_framework.schemas import get_schema_view
path(
    "schema/",
    get_schema_view(
        title="Your Project", description="API for all things ...", version="1.0.0"
    ),
    name="openapi-schema",
),
```

The code in the screenshot shows a Python import statement and a call to the `path` function. Inside the `path` function, there is a call to `get_schema_view` with parameters: `title="Your Project"`, `description="API for all things ..."`, and `version="1.0.0"`. The resulting object is assigned to the variable `name="openapi-schema"`.

# DRF-SPECTACULAR

- Old timers ! Uses drf-yasg but it's to old now ! Thus we use drf-spectacular
- <https://drf-spectacular.readthedocs.io/en/latest/>
- How to use it ?
  - A. pip install drf-spectacular
  - B. add it into installed apps in setting.py
  - C. set the default schema class
  - D. Add it spectacular to setting
  - F. using the documented path and replace it to schema in main urls.py

# DRF-SPECTACULAR

The 144<sup>th</sup> slide steps

I delet api in path too you  
can do it if you want!

Downloading schema

Graphical instructor

```
● ● ●  
A:  
  pip install drf-spectacular  
B:  
  
INSTALLED_APPS = [  
    'drf_spectacular',  
]  
C:  
REST_FRAMEWORK = {  
    'DEFAULT_SCHEMA_CLASS': 'drf_spectacular.openapi.AutoSchema'  
}  
D:  
SPECTACULAR_SETTINGS = {  
    'TITLE': 'Django Rest Project',  
    'DESCRIPTION': 'Your project description',  
    'VERSION': '1.0.0',  
}  
E:  
from drf_spectacular.views import SpectacularAPIView, SpectacularRedocView, SpectacularSwaggerView  
urlpatterns = [  
    # YOUR PATTERNS  
    path('api/schema/', SpectacularAPIView.as_view(), name='schema'),  
    # Optional UI:  
    path('api/schema/swagger-ui/', SpectacularSwaggerView.as_view(url_name='schema'), name='swagger-ui'),  
    path('api/schema/redoc/', SpectacularRedocView.as_view(url_name='schema'), name='redoc'),
```

# DRF-SPECTACULAR

- Now if we run it we can see it works!
- But it don't give us parameters and docstring therefore we have to override it in views and write description by writing docstring and for parameters
- For parameters :
  - Because drf-spectacular didn't know the serializer couldn't give us the needed parameters so we have to define serializer to it

# DEFINE SERIALIZER

Adding docstring

Define the serializer

```
class QuestionCreateView(APIView):
    """
    Create a new question and waiting for answer
    """

    permission_classes = [IsAuthenticated,]
    serializer_class = QuestionSerializer
```

# BEFORE/AFTER !

docstring

Parameters which  
shows from  
serialzier class

question

POST /question/create/

Parameters

No parameters

Responses

Code Description

200 No response body

question

POST /question/create/

Create a new question and waiting for answer

Parameters

No parameters

Request body required

application/json

Example Value | Schema

```
{ "title": "string", "slug": "66U6uzYjauJpgZC4agFLTYkZbCD-QdUf1ghBh5U733-NE6R2PT3n-Mle2hxclHd89uEZVC4-4zdWYBya_GKjeT+BP1-", "body": "string" }
```

Responses

Code Description

200

Media type application/json  
Controls Accept header

Example Value | Schema

```
{ "id": 1, "answers": 0, "user": "string", "title": "string", "slug": "string", "body": "string", "body_html": "string", "body_md": "string", "body_richtext": "string", "body_text": "string", "body_wysiwyg": "string", "body_xhtml": "string", "created": "2024-02-19T08:08:17.821Z" }
```

# REDOC

- Redoc is like swagger but have different ui ! Just that !
- Note : we used api view in our classes therefore it's need serializer class variable but list view or etc... has it by default . Api view couldn't identify serializer because we were writing it into our method

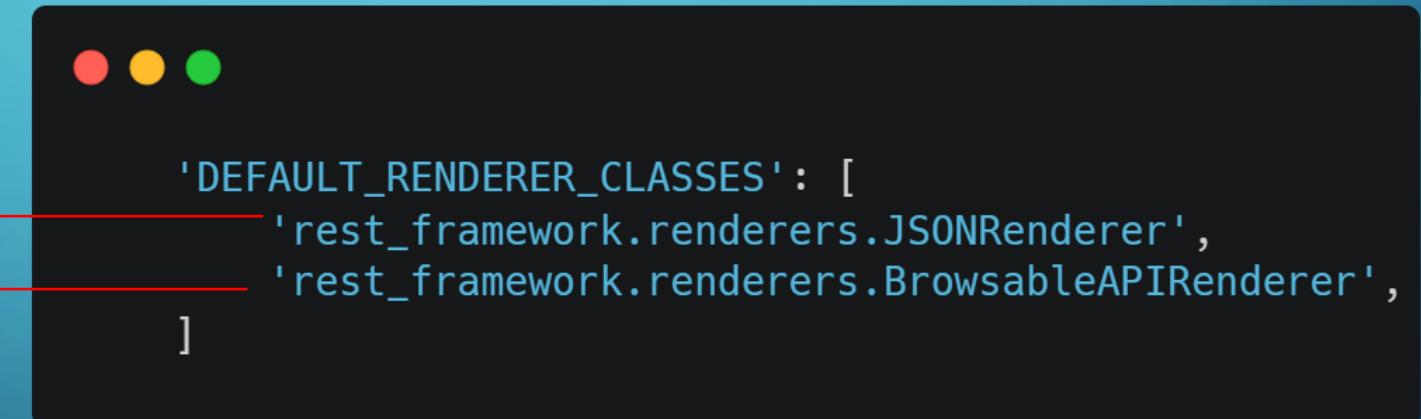

# RENDERS AND PARSERS

- Render and parser define how data transformation
- For example if we send request it's json and response is json too but we can change request by parsers and can change response by renders
- It could be YAML , XML, Json or etc.. By default it's json
- In browser there is another readable data type which call browsable api

# SETTING THE RENDER

- Just add it into `setting.py` in `rest_framework` part

Render gonna be json  
Render gonna be browsableapi

# TYPES OF RENDER

- Json render
- Template html render → if you have html page you can show it on html
- Static html render → you can show html code in static
- Browsable api render
- Admin render → just like admin panel in Django
- <https://www.django-rest-framework.org/api-guide/renderers/>

# SET A RENDER

- For setting the render there is an easy way in your `default_render_classes`
  - just type `rest_framework.renderers.name_of_render`

```
'DEFAULT_RENDERER_CLASSES': [  
    'rest_framework.renderers.JSONRenderer',  
    'rest_framework.renderers.AdminRenderer',  
    'rest_framework.renderers.BrowsableAPIRenderer',
```

# CUSTOM RENDER AND THIRD PACKAGE PARTY

- You can create your render or use TPP which allow us to use :
  - YAML
  - XML
  - ...
- In real world we just use Jsonrender
- Even we don't use browsable api render in production time

# PARSER

Just like renders !

```
REST_FRAMEWORK = {  
    'DEFAULT_PARSER_CLASSES': [  
        'rest_framework.parsers.JSONParser',  
    ]  
}
```

# PAGINATION

- Pagination use for partition of data's
- If you want to make your data dived to some parts you can use pagination
- For pagination we have 3 classes
  - A. page number pagination
  - B. limit offset pagination
  - C. cursor pagination (which it's useless... often!)
- If we use APIView or viewset we have to pagination manual but if we use generic pagination will automatically set on class

# ADDING PAGINATION

On setting.py!

```
REST_FRAMEWORK = {  
    'DEFAULT_PAGINATION_CLASS': 'rest_framework.pagination.LimitOffsetPagination',  
    'PAGE_SIZE': 100  
}
```

Also we change it  
in 2

In each page how much value you want to return

First we change it to pagernumberpagination

# PAGENUMBER PAGINATION

- Pagenumber pagination slice data by page number
- We add pagination on setting therefore it's not gonna effect on viewset and apiview just on generic view
- Just generic and model viewset handle it automatically

# GENERIC

This view writed by generic and it can handle pagination by adding pagination to settings

By page query params ( ?page = x ) categorize data

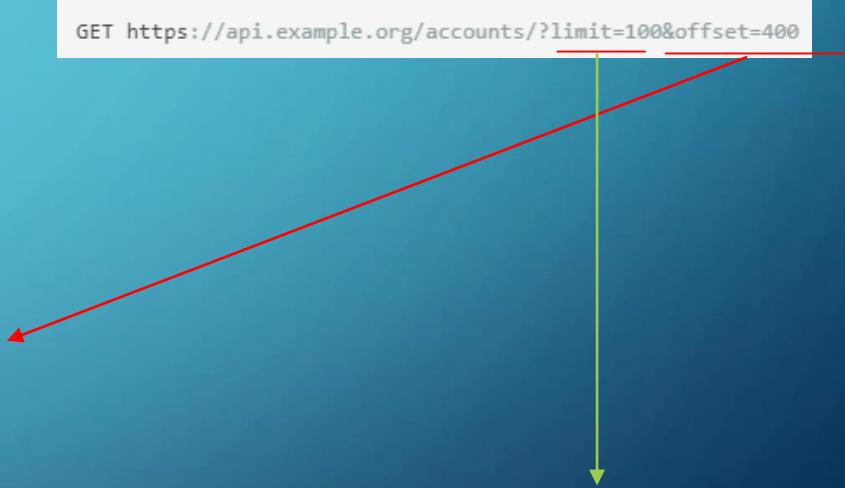

```
GET /accounts/users_list/  
  
HTTP 200 OK  
Allow: GET, HEAD, OPTIONS  
Content-Type: application/json  
Vary: Accept  
  
{  
    "count": 6,  
    "next": "http://127.0.0.1:8000/accounts/users_list/?page=2",  
    "previous": null,  
    "results": [  
        {  
            "id": 1,  
            "username": "root"  
        },  
        {  
            "id": 11,  
            "username": "amir"  
        }  
    ]  
}
```

# LIMIT OFFSET PAGINATION

Limit offset pagination getting 2 parameters offset and limit  
And we can change limit by changing it

It means howmuch values in database getting ignored. For example I have 500 records ,  
offset = 400 menas start showing me  
401 - 500 records

GET <https://api.example.org/accounts/?limit=100&offset=400>

Limit data in each page

# CUSTOM PAGINATION STYLE

- We can create our pagination class
- A. from rest\_framework.pagination import PageNumberPagination

Pagination class

Note : you have delete pagination  
settings in setting.py

Using pagination class

```
class Large(PageNumberPagination):  
    page_size = 2  
  
class UserListApi(generics.ListAPIView):  
    queryset = User.objects.all()  
    serializer_class = UserSerializer  
    pagination_class = Large
```

# USING PAGINATION ON API VIEW

- For api view we can use Django rest framework or Django !
- And we are going to use Django !!

Saying that get the page number from query params or set it 1 by default

A:

```
From django.core.paginator import Paginator
```

```
class UserApi(APIView):  
    def get(self, request):  
        queryset = User.objects.all()  
        page_number = self.request.query_params.get('page', 1)  
        srz_data = UserSerializer(instance=queryset, many=True)  
        return Response(data=srz_data.data)
```

# USING PAGINATION ON API VIEW

Getting limit from query params or by default set it as 2

```
class UserApi(APIView):
    def get(self, request):
        queryset = User.objects.all()
        page_number = self.request.query_params.get('page', 1)
        page_size = self.request.query_params.get('limit', 2)
        srz_data = UserSerializer(instance=queryset, many=True)
        return Response(data=srz_data.data)
```

```
class UserApi(APIView):
    def get(self, request):
        queryset = User.objects.all()
        page_number = self.request.query_params.get('page', 1)
        page_size = self.request.query_params.get('limit', 2)
        paginator = Paginator(queryset, page_size)
        srz_data = UserSerializer(instance=paginator.page(page_number), many=True)
        return Response(data=srz_data.data)
```

Using paginator class

Which variable going to be paginated?

What is pagination size?

# USING PAGINATION ON API VIEW

Now we send our paginator as instance and say that getting page from user or by default set it 1 (we set this settings on page number)

```
class UserApi(APIView):
    def get(self, request):
        queryset = User.objects.all()
        page_number = self.request.query_params.get('page', 1)
        page_size = self.request.query_params.get('limit', 2)
        paginator = Paginator(queryset, page_size)
        srz_data = UserSerializer(instance=paginator.page(page_number), many=True)
        return Response(data=srz_data.data)
```

# META DATA

- We use meta data when we want to Control on sent data's by OPTION method
- What is OPTION method ?
  - The OPTIONS method requests that the target resource transfer the HTTP methods that it supports. This can be used to check the functionality of a web server by requesting '\*' instead of a specific resource.
  - Sometime docstrings or etc... have important information and we don't want to show that on OPTION

# META DATA

- Meta data controls option to what data`s have to return and what not !

# CREATE CUSTOM METADATA CLASS

I create my metadata on permission.py  
You can create it anywhere

A:

```
from rest_framework.metadata import BaseMetadata
```

Name parameter : go to my view  
and get my view name

For renderer in my render  
class on view give me the  
media type

Same as  
renderer

```
class CustomMetadata(BaseMetadata):
    def determine_metadata(self, request, view):
        return {
            'name': view.get_view_name(),
            'renderers': [renderer.media_type for renderer in view.renderer_classes],
            'parsers': [parser.media_type for parser in view.parser_classes]
        }
```

# ADDING YOUR METADATA CLASS TO SETTINGS

```
REST_FRAMEWORK = {  
    'DEFAULT_METADATA_CLASS': 'permissions.CustomMetadata'  
}
```

File and class name ! (address it !)

# THANKS FOR YOU ATTENTION
